(54) Title: METHOD OF MULTIPLEX LIGASE CHAIN REACTION (57) Abstract The invention relates to multiplex ligase chain reaction (LCR). Two or more putative target sequences are selected. For each one, a set of four probes is used simultaneously to amplify the putative sequence if it is present in the sample. Preferably, all the amplicons are labeled with a common label/hapten and, for each different target, with a unique label/hapten. The invention also relates to an immunochromatographic strip device and method employing a diagonal array of capture spots.

Method of Multiplex Ligase Chain Reaction

Background:

This application relates to amplification of DNA and, in particular, to the simultaneous amplification of multiple target sequences using the Ligase Chain Reaction (hereinafter "LCR"). It is a continuation-in-part of co-owned and co-pending U.S. Serial No. 07/860,702 filed March 31, 1992, which is incorporated by reference.

This application is related to several other applications relating to LCR, including U.S. Serial No. 131,936 filed December 11, 1987, now pending; a continuation of that application, U.S. Serial No. 720,739 filed June 25, 1991, now pending; U.S. Serial No. 470, 674 filed January 26, 1990, now abandoned; and a continuation-in-part from that application, U.S. Serial No. 634,771 filed January 9, 1991; now pending. It is noted that published EP-A-320 308 corresponds to U.S. Serial No 131,936, and published EP-A-439 182 corresponds to U.S. Serial No. 634,771. Both of the published documents in their entirety are incorporated herein by reference.

LCR is a method for amplifying exponentially the number of detectable target molecules. It involves the use of two pairs of probes. A first or primary pair hybridizes with one strand of a target sequence at near-adjacent positions so that they can be ligated together in template-dependent fashion to form a reorganized primary molecule. The secondary pair is capable of hybridizing to the reorganized primary molecule. LCR was first described by Backman, et al. in EP-A-320 308. Much has been written about it since then. For example, see Wallace, EP-A-336 731; Orgel, WO 89/09835; Richards, WO 89/12696; Segev, WO 90/01069; and Barany, *Proc. Natl Acad Sci USA* 88:189-193 (1991). A variation of LCR known as "Gap" LCR is described in EP-A-439 182 and in Segev, WO 90/01069.

Instead of using two pairs of probes capable of forming blunt-ended duplexes, at least one probe of one of the probe pairs initially includes a "modified" end which renders the resultant duplex "nonblunt" and/or not a suitable substrate for the ligase catalyzed fusion of the two probe duplexes. A "modified end" has either (1) a blocking moiety (or additional base residues) on a group (e.g. the 5' phosphate or the 3' hydroxyl) which, under ordinary LCR conditions, obligatorily participates in the ligase catalyzed fusion or (2) omitted bases to create a "gap" between one probe terminus and the next probe terminus

In the "gap" embodiment, modified ends are created by eliminating from one or more of the probes a short sequence of bases, thereby leaving a recess or gap between the

-2-

5' end of one probe and the 3' end of the other probe when they are both hybridized to the target (or target complement, or polynucleotide generated therefrom). In order for LCR to amplify the target, the gaps between the probes must be filled in (i.e., the modification must be "corrected"). In a first version, this can be done using a polymerase or a reverse transcriptase and an excess of deoxynucleotide triphosphates which are complementary to the target strand opposite the gap. Alternatively, this can be done by supplying a fifth probe complementary to the target and a sixth probe complementary to the fifth probe.

PCR or polymerase chain reaction is a different method for amplifying DNA. It employs two primers which hybridize to opposite strands of a double stranded target. A polymerase initiates extension of the primer using the target as a template by sequentially adding the appropriate complementary nucleotides. PCR is described in U.S. Patents 4,883,195 and 4,883,202, the entire disclosures of which are incorporated herein by reference.

PCR has been used in a multiplex manner to determine the presence of multiple target sequences in a single reaction. EP-A-364 255 describes the use of multiple primer sets to simultaneously amplify multiple target sequences by PCR. A similar disclosure is made in Chamberlain, et al., *Nucl. Acids Res.*, 16:1141-56 (1988).

In addition, Nickerson, et al., *Proc. Natl. Acad. Sci. USA*, 87:8923-8927 (1990) proposes an oligonucleotide ligation assay ("OLA") for multiple target sequences, pending the development of "multiple, nonisotopic reporter groups". OLA employs two contiguous probes that are ligated together and the ligated product is detected as a measure of the presence of a target sequence.

In spite of the existence of these disclosures, multiplex LCR is not available in the hands of the public. The art does not provide sufficient guidance actually to enable the concept of multiplex LCR. This is due largely to the inapplicability of PCR conditions to LCR.

Summary of the Invention:

Accordingly, we have now demonstrated the feasibility of multiplex LCR with as many as seven different probe sets. In one aspect, the invention is a method for performing LCR amplification simultaneously on two or more target sequences. The method comprises the steps of:

- a. providing a reaction solution containing nucleic acid of a sample as single-stranded nucleic acid, said sample putatively having one or more of a plurality of target nucleic acid sequences;

-3-

b. for each putative target sequence, providing in the reaction solution at least four nucleic acid probes (a probe set), wherein: i) the first and second of said probes are primary probes, and the third and fourth of said probes are secondary nucleic acid probes; ii) the first probe is a single strand capable of hybridizing to a first segment of a primary strand of the target nucleic acid; iii) the second probe is a single strand capable of hybridizing to a second segment of said primary strand of the target nucleic acid; iv) the 5' end of the first segment of said primary strand of the target is positioned relative to the 3' end of the second segment of said primary strand of the target to enable joining of the first probe to the second probe when said probes are hybridized to said primary strand of said target nucleic acid, thus forming a reorganized primary molecule having a first portion and a second portion; v) the third probe is capable of hybridizing to a first portion of the reorganized primary molecule; and vi) the fourth probe is capable of hybridizing to a second portion of the reorganized primary molecule, the first portion of the reorganized primary molecule being positioned relative to the second portion of the reorganized primary molecule to enable joining of the third probe to the fourth probe when said third and fourth probes are hybridized to said reorganized primary molecule, thus forming a reorganized secondary molecule; and

wherein for each putative target sequence said probe set is provided at a concentration that enables said joining in the presence of each of the other probe sets; and

c. repeating the following cycle:

- i) hybridizing said probes with nucleic acid in said sample;
- ii) performing said joining to form said reorganized molecules; and
- iii) denaturing nucleic acid in said sample;

whereby with successive cycles the quantity of reorganized primary and secondary molecules is increased for each putative target sequence present in the reaction solution.

In the usual case, the joining is performed by a ligase enzyme, or a ligase enzyme and a polymerase enzyme. Usually, the cycle of step c is repeated from 10 to 100 times, preferably from 20 to about 60 times.

Generally, the amplification product is detected by means of a unique detectable label associated with each probe set, each of said detectable labels being differentiable from the others. Labels preferably include specific binding members, such as haptens or polynucleotides. The labels can be used for either detection, or separation or both. In a preferred configuration, each of the probe sets are labeled with two distinct labels such that the reorganized molecules, when hybridized together, are labeled with two labels, at least one of which is a unique label and the other label is a common label, the same for each probe set.

-4-

In a preferred protocol, the common label is used for detection and the unique label is used to separate the reorganized molecules of one probe set from the reorganized molecules of at least one other probe set. Separation may be accomplished by different binding locations on a single solid phase, or by using a solid phase which is characterized by a property which permits differentiation of one from another.

In a second aspect, the invention is a method of detecting the presence, absence or quantity of each of a plurality of target nucleic acid sequences by a multiplex ligase chain reaction comprising the steps of:

- a. providing a reaction solution containing nucleic acid of a sample as single-stranded nucleic acid, said sample putatively having one or more of a plurality of target nucleic acid sequences;
- b. for each putative target sequence, providing in the reaction solution a set of at least two and optionally four nucleic acid probes (a probe set), wherein: i) the first and second of said probes are primary probes, and the optional third and fourth of said probes are secondary nucleic acid probes; ii) the first probe is a single strand capable of hybridizing to a first segment of a primary strand of the target nucleic acid; iii) the second probe is a single strand capable of hybridizing to a second segment of said primary strand of the target nucleic acid; iv) the 5' end of the first segment of said primary strand of the target is positioned relative to the 3' end of the second segment of said primary strand of the target to enable joining of the first probe to the second probe when said probes are hybridized to said primary strand of said target nucleic acid, thus forming a reorganized primary molecule having a first portion and a second portion; v) the third probe is capable of hybridizing to a first portion of the reorganized primary molecule; and vi) the fourth probe is capable of hybridizing to a second portion of the reorganized primary molecule, the first portion of the reorganized primary molecule being positioned relative to the second portion of the reorganized primary molecule to enable joining the third probe to the fourth probe when said third and fourth probes are hybridized to said reorganized primary molecule, thus forming a reorganized secondary molecule;

wherein at least one probe of each probe set contains a detectable label, the detectable label associated with each probe set being differentiable from the detectable labels associated with the other probe sets, whereby the presence, absence or quantity of each putative target sequence can be determined; and

wherein for each putative target sequence said probe set is provided at a concentration that enables said joining in the presence of each of the other probe sets; and

- c. performing the following cycle:
 - i) hybridizing said probes with nucleic acid in said sample;

-5-

- ii) performing said joining to form said reorganized molecules; and
- iii) denaturing nucleic acid in said sample;

whereby with each cycle the quantity of reorganized primary and, optionally, secondary molecules is increased for each putative target sequence present in the reaction solution; and

d. measuring the detectable label associated with each of said probe sets as a measure of the presence or quantity of target nucleic acid in the reaction solution.

The same variations of labeling, separation and detection mentioned above are useful for this aspect of the invention.

Finally, the invention relates to an immunochromatographic device and method for multiplex detection of multiple analytes. The device comprises a strip of porous material capable of transporting fluids by capillary action, said strip having at least first and second unique capture reagents immobilized thereon in first and second discrete spots spaced apart from an end used to contact transport fluid, said unique first and second capture reagents being specific different first and second analytes, respectively, wherein said second discrete spot is spaced from said first discrete spot in both vertical and horizontal dimensions, vertical being the direction of fluid flow. Preferably, the device contains three or more discrete spots, and said spots are all spaced from one another in both vertical and horizontal dimensions to form a substantially linear, diagonal array of spots.

The method of using the device involves contacting said contact end with a test solution suspected to contain the analyte under conditions that allow said solution to be transported by capillary action at least to the most distal capture spot; and determining for each capture spot, whether analyte became bound to said capture spot.

The method and device are useful for conventional specific binding analytes, such as antigens and antibodies, as well as for polynucleotide analytes.

Brief Description of the Drawings:

Fig 1 is a diagram of the immunochromatography strip used in multiplex LCR detection.

Figs 2a and 2b are photographs showing the immunochromatographic strip results of multiplex LCR performed on patient samples from example 7

Fig 3 is a photograph showing the immunochromatographic strip results of multiplex LCR performed on patient samples from example 10.

Detailed Description:

As used in this application, a "multiplex" process refers to the carrying out of a method or process simultaneously and in the same reaction vessel on two or more, typically three or more, different target sequences. Thus, multiplex LCR is the performance of LCR on a plurality of targets using at least one set of four probes for each putative target sequence. In like manner, the term "N-plex" LCR, where N is a numeral, refers to LCR performed to amplify or detect one or more of N target sequences.

A "target sequence" or "target nucleic acid" is a segment of nucleic acid (DNA or RNA). The segment may be from about 10 or 15 to several hundred nucleotides in length. For LCR, a target segment is usually about 30 to about 60 nucleotides and the sequence is known. A target is "putative" if its presence is expected or anticipated, or if it or a variation of it is expected or anticipated. For example, in multiplex LCR of a homozygote to determine which of two mutually exclusive alleles is present, the sequences surrounding both alleles are putative target sequences, even though it is known that only one is expected to be present. The possible alternatives for each allele are all putative targets.

The step of "joining" as recited above encompasses several known methods of joining two probes together. The preferred method is by the use of a thermostable ligase, although other ligases and other ligating agents are not excluded. Ligases are discussed in the incorporated EP-A-320 308 and in EP-A-373 962 which is also incorporated by reference. Joining is also possible by chemical means or by photoligation. Joining also encompasses the possible intermediate step of "correcting" a modified end as taught in the incorporated EP-A-439 182. Correction includes the filling of a gap with an extending reagent (such as polymerase) as well as the cleaving of a blocking group (such as with endonuclease IV).

A reaction solution is typically prepared by collecting the sample from a patient and disrupting the cells to release the DNA or RNA. Detergents may be used, but other known methods of sample preparation are also included. Specific buffer compositions are available from the literature, and from the examples. The DNA or RNA is rendered single-stranded by altering the stringency conditions, usually by heating.

The probes for multiplex LCR are generally no different than the probes for conventional LCR. However, to facilitate detection at least one probe of each probe set should bear a detectable label. Moreover, the detectable labels from each of the probe sets must all be differentiable, one from the other, either by signal differentiation or by spatial differentiation. As is described in more detail below, signal differentiation refers to the ability to distinguish targets in essentially the same location (i.e. homogeneous assay) by virtue of differences in the signal (e.g. different fluorescent emission wavelengths or

-7-

different colors). By contrast, spatial differentiation refers to the ability to distinguish targets based on the position or location of the signal. Spatial differentiation is also known as separation and may be accomplished by size, molecular weight, charge density, or magnetic or specific binding properties, and the like. Of course, it is possible and often desirable to utilize both types of differentiation within the same system.

Where separation is preferred in order to interpret the results, a preferred embodiment uses two labels: at least one of which is a unique or differentiable label. The other label may be common, and shared by each of the probe sets, or it may be unique as well. Depending on the particular protocol used (see below), either the common label or the unique label may be used for detection, and the other label may be used for separation.

The term "label" refers to a molecule or moiety having a property or characteristic which is capable of detection. A label may be directly detectable, as with radioisotopes, fluorophores or chemilumiphores; or a label may be indirectly detectable, as with haptens or polynucleotide tails. When indirect labels are used for detection or signalling purposes, they are used in conjunction with a signalling entity complex. A "signalling entity" is a molecule or moiety which provides the detectable property or characteristic. The signalling entity may be direct, as with a colloidal particle (e.g. colloidal gold or selenium); or it may be indirect, as with an enzyme (e.g. alkaline phosphatase, β -galactosidase or horseradish peroxidase). Indirect signalling entities may require additional components, e.g. substrate, as is well known in the art. The "signalling entity complex" includes a signalling entity conjugated to specific binding partner, such as an antibody or polynucleotide. Such conjugates may be prepared according to any known method of conjugation.

Useful labels include radioisotopes, especially as the common label. However, it may be possible to use a radioisotope as a unique label when the radiation can be differentiated. Likewise, fluorophores and chemilumiphores are best used as common labels, although it would be possible to use them as unique labels if their signal can be differentiated (e.g. on the basis of wavelength). A hapten, polynucleotide or other specific binding member may also serve as the common label, although the ability to easily distinguish one specific binding member from another renders them ideally suited for the unique label. When different specific binding members are employed, conjugates bearing different specific binding partners are used according to one of the protocols described below.

Many different haptens are known, and virtually any hapten can be used with the present invention. The invention requires only that a specific binding partner is known or can be prepared (a definitional property of "hapten") and that the hapten can be coupled to the probe such that it does not interfere with hybridization. Many methods of adding

-8-

haptens to probes are known in the literature. Enzo Biochemical (New York) and Clontech (Palo Alto) both have described and commercialized probe labelling techniques. For example, a primary amine can be attached to a 3' oligo end using 3'-Amine-ON CPG™ (Clontech, Palo Alto, CA). Similarly, a primary amine can be attached to a 5' oligo end using Aminomodifier II® (Clontech). The amines can be reacted to various haptens using conventional activation and linking chemistries.

In addition, co-pending applications U.S. Serial Nos. 625,566, filed December 11, 1990 and 630,908, filed December 20, 1990 teach methods for labelling probes at their 5' and 3' ends respectively. Both the aforementioned co-pending applications are incorporated by reference. Some illustrative haptens include many drugs (eg. digoxin, theophylline, phencyclidine (PCP), salicylate, etc.), T3, biotin, fluorescein (FITC), dansyl, 2,4-dinitrophenol (DNP); and modified nucleotides such as bromouracil and bases modified by incorporation of a N-acetyl-7-iodo-2-fluorenylamino (AIF) group; as well as many others. Certain haptens described herein are disclosed in co-pending, co-owned patent applications U.S. 07/808,508 (adamantaneacetic acids), U.S. 07/808,839 (carbazoles and dibenzofurans), both filed December 17, 1991, U.S. 07/858,929 (acridines); and U.S. 07/858,820 (quinolines), both filed March 27, 1992 (collectively referred to herein as the "haptens applications"). The entire disclosure of each of the above haptens applications is incorporated herein by reference.

It should be understood that the number of probes necessary for multiplex amplification or detection is generally four times the number of putative sequences. In the case of an assay for "N" different bacterial organisms, the number of probes required is $4 \times N$. In the case of genetic testing of mutations, the rule of $4 \times T$ probes, where T is the number of putative targets, is still the general or usual case. However, certain exceptions are described below. It should be kept in mind that, depending on the type and complexity of the mutation, there may be several putative targets for each mutation. Take for example, a simple, single base substitution. If it is known that the substitution is always one type of base, the possible putative target sequences are two: the wild type and the mutation substitution. However, if it is known that any of the four bases can substitute at the locus, then the putative target sequences become four. The general rule requires eight ($4 \times T$, $T=2$) probes in the first case; and 16 ($4 \times T$, $T=4$) probes in the second.

The general rule of four probes for each putative target will hold regardless of the type and complexity of the mutation. However, in some simple mutations two probes from one set (say, arbitrarily, the right two) will also serve as the two (right) probes from the other sets and fewer than $4 \times T$ probes will be required. These simple mutations include any small deletion, insertion or substitution the ends of which are known with certainty. So

long as the ends are known, the size of the deletion, insertion or change does not affect its characterization as "simple". With these "simple" mutations, the number of probes required is $(2T+2)$. The +2 is the common probe set on one side of the mutation, while the 2T represents all the possible permutations of the mutation, i.e all the possible putative target sequences. Of course, the number of possible permutations depends on the nature of the mutation.

Another "special case" where less than 4T probes are required is possible where the mutation configuration of the gene is such that two mutations are near enough to one another that a common probe can be used between the two mutations, with specialized probes on the outside ends. "Near enough" in this context means within a distance that can be spanned by an LCR probe. Typically, that distance is about 20 to 40 bases.

Interpretation of LCR results may include looking at the number of cycles required to produce target and background curves that are distinguishable from one another. For a given concentration of probes, the background signal will develop after n cycles, while the target signal develops after only t cycles. In order for LCR to be useful as a diagnostic tool, it is desired that n be far greater than t , i.e. that there be as large a "cycle window" as possible between target and background. see, e.g. EP-A-320 308. It has also been shown that the cycle number at which signal "comes up" varies with probe concentration: The higher the probe concentration, the sooner the signal comes up, and vice versa. As a consequence, it has been discovered that it is preferable to balance the probe concentration carefully in multiplex LCR. Since all reactions are run for the same number of cycles, all target signals must "come up" at approximately the same time. This can be insured by carefully balancing the concentration of each probe set so that each reaction reaches peak or at least detectable signal levels at approximately the same cycle number. It is impossible to predict precisely how to adjust probe concentration for a given probe set, but this can readily be determined empirically through simple experiments.

It is generally known that the melt temperature of the probe sets for LCR should be approximately equal. However, it has been discovered in multiplex LCR that the melt temperatures may vary by as much as 8 to 10° C from one side to the other.

Other reaction conditions for multiplex LCR are similar to those used for more fundamental LCR. The same buffer, pH and salt conditions are generally acceptable. However, it is desirable to add a somewhat higher concentration of ligase, as shown in the examples. In addition, if gap filling LCR is used, additional polymerase may be desired as well.

As mentioned above, the most preferred protocols include two labels, a common label and a unique label. Either may serve as the detection label. For simplicity, the

-10-

embodiments are described using haptens as both the common and unique labels. It is, of course, understood that another label is easily substituted for at least one of the haptens, especially the common hapten.

According to a preferred standard LCR protocol, a first hapten is used to capture and separate the reorganized molecules. A second hapten is used to couple the reorganized complex with the signalling entity. This procedure is described more completely in EP-A-439 182. For example a fluorescein moiety is attached to the 5' end of the first primary probe and to the 3' end of the first secondary probe. In addition, a different hapten, say biotin, is attached to the 3' end of the second primary probe and to the 5' end of the second secondary probe. Thus, when the reorganized molecules are duplexed, two biotins are found at one end of the duplex and two fluoresceins are found at the other end. A solid phase having a coating of anti-fluorescein is used to separate reorganized molecules from unligated probes having biotins. (Unligated probes having fluoresceins are also captured.) The separated complexes are detected by using avidin or anti-biotin labeled with a detectable signalling entity such as an enzyme.

For multiplex LCR this system of separation and detection need only be slightly modified. It is still possible to use just one hapten common to all probe sets at one end (detection or capture) of the reorganized molecules. Only the other end of the molecules needs to be differentiable, e.g. via a unique hapten. Two distinct protocols are possible.

First, the common hapten (say, biotin) could be used to capture all the reorganized molecules. Then the different complexes can be differentiated by using specific haptens, and anti-hapten conjugates with differentiable signalling entities. For example (paying attention to the orientation and proper probe end considerations mentioned above) probes for target A are labeled with biotin and fluorescein; probes for target B are labeled with biotin and dansyl; and probes for target C are labeled with biotin and digoxin. All reorganized molecules (and biotinylated probes) are captured on a solid phase. Anti-fluorescein coupled to colloidal gold produces a reddish brown color if target A is present; anti-dansyl coupled to colloidal selenium produces a pinkish color if target B is present and anti-digoxin coupled to polypyrrole latex produces a black color if target C is present. As an alternative, the antibodies can be coupled to different enzymes (eg. alkaline phosphatase, peroxidase, β -galactosidase) the substrates or products of which produce different colors.

Since discerning different colors on a single solid phase may be difficult, a second and more preferred protocol involves using the common hapten/label as the detection function and using the unique hapten to separate the targets from one another on one or more solid phases. For example, beads or microparticles which can be physically separated (eg. by manipulation, filtration, chromatography, sedimentation, centrifugation,

-11-

magnetic field, etc.) may be used as a solid phase. Separable groups of these solid phases are each coated with antibody against one of the unique haptens. After multiplex LCR and incubation with the solid phases, the groups are separated and a common signalling entity complex is reacted with the common hapten. Different sequences are determined by the appearance of signal on one or more of the different solid phase groups.

5 A dot-blot method is also useful to separate reorganized molecules. To discrete locations on a sheet-like solid phase are immobilized antibodies to the several unique haptens. Incubation of this sheet with the reaction solution will permit separation of the reorganized molecules, based on the specificity of the antibodies for the unique haptens. Again, the common hapten is employed with a signalling entity conjugate to generate signal at any location which contains a reorganized molecule. The solid phase is interpreted based on the location (and optionally the intensity) of the signal.

10 A variation of this technique employs immunochromatography to separate the reorganized molecules on the basis of the unique hapten. Rather than incubate the solid phase with the reaction solution, the solid phase is a porous chromatographic material and the reaction solution wicks through it, drawn by capillary action. A preferred porous material is nitrocellulose. As with the dot-blot method, antibody to each unique hapten is immobilized at various locations throughout the strip, preferably along a diagonal line. When the reaction solution carrying all the reorganized molecules encounters an immobilized antibody spot, the reorganized molecules bearing the complementary hapten are "captured" and immobilized at that location. This technique is a variation of the technique described in EP-A-357 011, the entire disclosure of which (and particularly those aspects relating to immunochromatographic detection of target nucleic acid) is incorporated by reference. The following examples demonstrate this technique.

15 It has been found that the immunochromatography method works best when the capture spots for various polynucleotide targets (and even regular analytes) are aligned in a diagonal configuration as shown in Figure 1. It is desirable to spatially separate capture spots in both dimensions for several reasons. First, vertical separation is useful to better differentiate signals from adjacent spots. However, if the spots are spaced only in this dimension, there is a tendency for label to accumulate at the first positive capture spot. Spots downstream from this spot are "shadowed" and generally do not develop signal as readily. Thus, it is preferred to separate spots in a horizontal direction as well. Spots spaced only in a horizontal direction would require a much wider strip in order to achieve the resolution necessary to read the strip.

20 In yet another variation of either protocol the reorganized molecules can be separated and/or detected by sequence-specific probe hybridization instead of haptens.

-12-

This variation is possible with the separable groups of solid phases, with the sheet-like solid phase and with the chromatographic medium. The only difference is that, instead of immobilizing a unique hapten-specific antibody on the solid phase, a hybridization probe is immobilized, the probe being specific for sequences found in the first primary and or first
5 secondary probes (ie. the same probes which carried the unique hapten in the prior variation). The method of chromatographic medium specific hybridization is described further in EP-A-387 696, the entire disclosure of which (and particularly those aspects relating to immunochromatographic detection of analytes) is incorporated herein by reference.

10 The multiplex LCR method of the present invention has numerous applications, depending on the type of target employed. First, it is useful in genetic screening or testing. Often a particular genetic disease or trait manifests itself as a mutation or change in the genetic code at one or a finite number of locations in the genome. Some diseases or conditions (e.g. sickle cell anemia, phenylketonuria, Tay-Sachs disease, medium chain acyl
15 CoA dehydrogenase deficiency, cystic fibrosis) manifest themselves as a point mutation of a single base in the DNA. Others (e.g. cystic fibrosis, Duchene's Muscular Dystrophy (DMD)) can manifest themselves by short alterations or deletions in one or a relatively small number of exon locations. The ability to do multiplex LCR permits the simultaneous analysis of an individual's DNA at each of the exons where deletions/alterations are known
20 to be causative for a particular disease.

Another use for multiplex LCR is in the diagnosis of certain bacterial or viral diseases which typically occur from many variant strains of an infecting organism or virus. For example, human papilloma virus (HPV) types 6, 8, 11, 16, 18, 31, and 33 are all known to exist. Universal or consensus probes and primers will amplify all HPV
25 regardless of type. However, only types 16, 18 and possibly 33 are of significant clinical interest due to their association with cancerous lesions. Thus, a multiplex LCR assay permits the simultaneous type-specific amplification of each variant. This gives the clinician additional information not available from simple universal amplification or from simple type-specific amplification of one type. This approach is also useful for HIV,
30 which has at least two known types; and for *Chlamydia trachomatis*, which has at least 15 serovars.

It may also be useful to perform multiplex LCR when only a single organism is of interest. For example, multiple target sequences may be picked for confirmation or improved specificity. For example, sequences from both the MOMP gene and the cryptic
35 plasmid might be selected to detect *C. trachomatis* DNA. Alternatively, internal controls

-13-

might be run by including probes that will amplify β -globin sequences, as well as probes that will amplify the desired target.

Another use for multiplex LCR is in identity testing. A panel of perhaps 10 or more sequences may be selected which are highly variant in the general population. By
5 determining the presence or absence of each of these sequences, an individual may be "typed" with a unique pattern of presence or absence of each particular exon sequence. In a binary format, individual "A" is identified as "0111001001", while individual "B" is identified as "0000111011", where a "0" indicates the absence of a particular exon sequence and a "1" indicates the presence of a particular exon sequence.

10 Other uses will be readily apparent to those skilled in this art.

EXAMPLES

The invention will be more completely understood with reference to the following examples which are intended to be illustrative only, and do not limit the invention.

15 Throughout the examples the following abbreviations have the meanings given.

- BSA refers to bovine serum albumin.
- EPPS refers to a buffer of N-(2-hydroxyethyl)piperazine-N'-(3-propanesulfonic acid).
- 20 • NAD refers to nicotinamide adenine dinucleotide, an energy source for certain biological reactions.
- PCR refers to the polymerase chain reaction
- TRIS refers to *tris*- (hydroxymethyl)aminomethane buffer.
- TTP refers to thymidine triphosphate, one of the substrates for polymerase.
- 25 • Abbott TestPack Plus™ is a trademark of Abbott Laboratories used to designate a chromatographic or wicking type of immunoassay. This assay format is described in further detail in EP-A- 421 294 and EP-A-357 011, as well as in other literature.

30 Example 1: Oligo Synthesis and Haptenation

Part A - Sequence and Synthesis:

The following oligonucleotides (see Table 1) were synthesized following established procedures using β -cyanoethylphosphoramidites on a model 380A DNA synthesizer (Applied Biosystems, Foster City CA), where x = primary amine derived from
35 3'-Amine-ON CPG™ (Clontech, Palo Alto, CA), y = primary amine derived from Aminomodifier II® (Clontech), p = phosphate derived from Phosphate-ON® (Clontech),

-14-

and A,C,G, and T have their usual meanings. Probes are written 5' to 3' from left to right. Melting temperatures are given for probe pairs as follows: first and second hybridize, and third and fourth hybridize.

5

Oligos 1-4 are specific for a portion of exon 4 of the Duchenne Muscular Dystrophy (DMD) gene, following the numbering scheme described by Koenig M, Monaco AP, and Kunkel, LM. in *The complete sequence of dystrophin predicts a rod shaped cytoskeletal protein*. Cell 53, 219-228 (1988). According to the same numbering scheme, oligos 5-8 are specific for a portion of exon 8 of the Duchenne Muscular Dystrophy gene; oligos 9-12 are specific for a portion of exon 12 of the DMD gene; oligos 13-16 are specific for a portion of exon 17 of the DMD gene; oligos 17-20 are specific for a portion of exon 19 of the DMD gene; oligos 21-24 are specific for a portion of exon 44 of the DMD gene; oligos 25-28 are specific for a portion of exon 45 of the DMD gene; oligos 29-32 are specific for a portion of exon 48 of the DMD gene; and oligos 33-36 are specific for a portion of exon 51 of the DMD gene. Oligos 37-40 are specific for a portion of the human β -globin gene and are used as a control.

Part B - Haptenation

The 3'-end of some oligonucleotides were conjugated with haptens, as indicated in Table 1. The conjugation of these haptens followed standard β -cyanoethyl-phosphoramidite chemistry, and is described in the aforementioned hapten applications. A similar procedure is described for fluorescent label conjugates in published U.S. application NTIS ORDER No. PAT-APPL-7-246,688) (Cohen, et al., 1989). The structures of the haptens used are shown in Table 2, below:

-16-

Table 2

Hapten	Structure
acridine	
dansyl	
dibenzofuran	
fluorescein	

-17-

quinoline	
thiophene carbazole	

All oligonucleotides were purified by reversed-phase HPLC to remove failure sequences and, in the case of haptenated oligos, any unhaptenated species.

5 Example 2: Biotinylation

The aminated ends of oligos 3, 4, 7, 8, 11, 12, 15, 16, 19, 20, 23, 24, 27, 28, 31, 32, 35, 36, 39, and 40 from example 1 were labeled with biotin essentially following the protocol of Urdea, *et. al.*, *Nucl. Acids Res.*, **16(11)**:4937-4956 (1988). Briefly, up to 1 mg oligo was dissolved in 100 μ L of 0.1 M sodium phosphate buffer, pH 7.5, and treated with 2 mg biotin-(aminocaproyl)2-N-hydroxysuccinimide ester in 100 μ L dimethylformamide (DMF) for 16 hours at room temperature.

Oligos 22 (3' end) and 33 (5' end) were linked to fluorescein after synthesis by dissolving up to 1 mg oligo in 100 μ L of 0.1 M sodium borate buffer, pH 9.0, and treating with 2 mg of fluorescein isothiocyanate (FITC) for 15 hours at room temperature. Alternatively, the 3' aminated end of oligo 34 could be reacted with FITC, rather than haptenating oligo 33.

All biotin- and fluorescein-labeled oligonucleotides were purified by column chromatography through Sephadex[®] G-25 (Pharmacia, Piscataway NJ), preparative gel electrophoresis, and ethanol precipitation.

For quality control purposes, the integrity of reorganized molecules after performing LCR was monitored on the IMx[®] instrument (Abbott Labs) using the typical biotin/fluorescein bihaptenated complex as taught in EP-A-439 182. For this reason, oligos 1, 9, 13, 17, 21, 25 and 29 were synthesized with a 5' primary amine. Portions of

-18-

these oligos were reacted with fluorescein, as above, to provide the biotin/fluorescein complex necessary for IMx analysis. However, when used in multiplex LCR, the unhaptenated, aminated oligos were used.

5 Example 3: LCR Reaction Conditions

The labeled oligos of example 2 were used, in various combinations, in "gap filling" modified LCR essentially as described in EP-A-439 182. In general, the following reagents were mixed in a 0.5 mL polypropylene tube:

10	<u>Reagent</u>	<u>Final Concentration</u>
	water	(to give a final volume of 45 μ L)
	reaction buffer	15 mM EPPS pH 7.8
		20 mM KCl
15		30 mM MgCl ₂
	oligonucleotides	see Table 3
	NAD	0.1 mM
	TTP	1 μ M
	sample	250 ng DNA
20	mineral oil	2 drops/tube

The mixture was heated at 100°C for 3 minutes, cooled, and the following were added in a volume of 5 μ L, to give a final reaction volume of 50 μ L:

25	<u>Reagent</u>	<u>Final Concentration</u>
	DNA ligase	3400 U/50 μ L
	from <i>Thermus thermophilus</i>	
	DNA polymerase	1.2 U/50 μ L
30	from <i>Thermus</i> (MBR Inc., Milwaukee WI)	

The mixture was then subjected to 37 cycles of programmed temperature change, the cycle being 85°C for 30 seconds and 45°C for 20 seconds. The thermal cycling was carried out in a TempCycler™ (Coy Laboratory Products, Ann Arbor MI).

35

-19-

Table 3

To Detect This Exon	Use These Oligos	At These Concentrations (number of molecules of each oligo per reaction tube (50 μ L))
Exon 4	1-4	1.5×10^{12}
Exon 8	5-8	7.7×10^{11}
Exon 12	9-12	3.8×10^{11}
Exon 17	13-16	7.7×10^{11}
Exon 19	17-20	7.7×10^{11}
Exon 44	21-24	3.8×10^{11}
Exon 45	25-28	3.8×10^{11}
Exon 48	29-32	3.1×10^{11}
Exon 51	33-36	3.8×10^{11}
β -globin	37-40	7.7×10^{11}

Example 4: Antibodies and Solid Phase

Antiserum was raised in rabbits against immunogens prepared from conjugates of hapten and either bovine serum albumin (BSA) or keyhole limpet hemocyanin (KLH). The preparation and description of these sera is described in the above-mentioned hapten applications, although any known procedure for raising antibodies would suffice. These sera were purified by passage through protein A Sepharose® (Pharmacia).

Antiserum against dansyl was a mouse monoclonal obtained from the University of Pennsylvania (Fan, S-T. and Karush, F. *Molecular Immunology* 21:1023-1029 (1984)).

These antisera were diluted in 0.1 M TRIS pH 7.8, 0.9% NaCl, 0.1% BSA, 1% sucrose, and a trace of phenol red. Portions (0.2 μ L) of these diluted antisera were spotted in a regular pattern (see Figure 1) onto strips of nitrocellulose (Schleicher and Schuell AE 98, 5 μ m) of dimensions approximately 4 x 50 mm. The concentrations of antisera were as indicated in Table 4.

Table 4

antiserum against	concentration (mg/mL)
acridine	2.55
dansyl	0.5
dibenzofuran	3.4
fluorescein	0.5
quinoline	0.75
thiophene carbazole	0.25

-20-

Example 5: Label Conjugate

Colloidal selenium was prepared following the procedure of Yost, D.A. *et. al.* (U.S. patent 4,954,452 (1990)). The colloid was diluted in water to achieve an optical density of 16 at 545 nm. To 1 mL of this suspension was added 1 μ L of antibiotin (Abbott Laboratories) at 1 mg/mL and 60 μ L of BSA at 100 mg/mL. This mixture was mixed on a vortex mixer for 1 minute.

Example 6: Multiplex Immunochromatography

The LCR reaction mixtures of Example 3 were analyzed by Abbott TestPack PlusTM immunochromatography essentially following the protocol of EP-A-357 011. Briefly, the colloidal suspension of Example 5 (15 μ L) was diluted with buffer (14 μ L; 0.1 M TRIS pH 7.8, 0.9% NaCl, 3% alkali-treated casein) and mixed with the product of the LCR reaction (1 μ L). A nitrocellulose strip of Example 4 was admitted to the suspension. After 5 minutes, the chromatography process was complete, and the nitrocellulose strip was removed from the reaction/colloid suspension and allowed to dry. The presence of a colored spot at the locus of antibody application indicated the presence of a specific LCR product.

Example 7: Analysis of Patient Samples for DMD

Samples of human DNA obtained from patients with Duchenne Muscular Dystrophy were analyzed for the presence of exons 4, 12, 17, 19, 44, 45, 48, and 51 using oligos 1-4 and 9-36. Oligos 37-40 were included in the reaction mix as a procedural control to detect the presence of human DNA. The analysis of each sample was performed in two parts: in one reaction tube was the mixture described in Example 3 containing oligos 13-28 and 33-40 (to amplify exons 17, 19, 45, 48, and 51; along with human β -globin); and in another tube was the LCR reaction mix containing oligos 1-4, 9-12, 29-32, and 37-40 (to amplify exons 4, 12, and 44; along with human β -globin). These analyses were performed by subjecting the sample DNA to LCR following Example 3, and subsequently immunochromatography of the resulting mix following Example 6.

In Figure 2 are shown photographs of nitrocellulose strips after immunochromatography. The photograph of Figure 2a shows 7 nitrocellulose strips. These show the presence of amplification products specific for (spots from bottom to top) human β -globin, and DMD exons 17, 45, 48, 51, and 19. The samples contained 250 ng of DNA from, respectively (from left to right): salmon sperm DNA; 5 individual patients suffering from Duchenne Muscular Dystrophy (patient numbers indicated in the photograph), and normal human DNA. Similarly, the photograph of Figure 2b shows 5

-21-

nitrocellulose strips. These show the presence of amplification products specific for (spots from bottom to top) human β -globin, and DMD exons 12, 4, and 44. The samples contained 250 ng of DNA from, respectively (from left to right): salmon sperm DNA; 3 individual patients suffering from Duchenne Muscular Dystrophy (patient numbers not indicated in the photograph— these are (from left to right) patients 5294, 4036, and 638), and normal human DNA.

The missing exons for each patient are known from PCR (see Table 5).

Table 5

Patient Number	Exons Deleted (by PCR) <i>all others will be amplified</i>
4722	17, 19, 45, 48, and 51 (44 not tested)
5294	4, 12, 17 and 19
5303	45
5396	51
638	4, 12, 17, 19, 44, and 45
4036	12 and 44 (17, 19, 45, 48, and 51 not tested)

10 Example 8: Oligo Synthesis for cystic fibrosis

The following oligonucleotides (see Table 6) were synthesized following established procedures using β -cyanoethylphosphoramidites on a model 380A DNA synthesizer (Applied Biosystems, Foster City CA), where p = phosphate derived from Phosphate-ON® (Clontech), biotin is introduced using Biotin-ON® (Clontech), and A,C,G, and T have their usual meanings. Probes are written 5' to 3' from left to right. Haptentation as indicated was performed as described in Example 1.

-22-

Example 9: LCR Reaction Conditions

5 The labeled oligos of example 8 were used for blunt LCR essentially as described in EP-A-320-308 using the following concentrations of reagents:

	Reagent	Final Concentration
10	water reaction buffer	(to give a final volume of 45 μ L) 50 mM EPPS pH 7.8 150 mM KCl 10 mM MgCl ₂
15	oligonucleotides 41, 42, 43, and 44 oligonucleotides 45, 46, 47, and 48 oligonucleotides 49, 50, 51, and 52 NAD BSA	3.3x10 ¹¹ copies of each 4.2x10 ¹¹ copies of each 2.7x10 ¹¹ copies of each 0.1 mM 5 μ g
20	sample mineral oil	250 ng DNA 2 drops/tube

-23-

The mixtures were heated at 100°C for 3 minutes, cooled to room temperature, and the following were added in a volume of 5 µL:

5	<u>Reagent</u>	<u>Final Concentration</u>
	DNA ligase from <i>Thermus thermophilus</i>	3400 U/50 µL

10 The mixture was then subjected to 45 cycles of programmed temperature change, this cycle being 85°C for 30 seconds and 57°C for 20 seconds. The thermal cycling was carried out in a TempCycler™ (Coy Laboratory Products, Ann Arbor MI).

Example 10: Analysis of Patient Samples for cystic fibrosis mutations

15 Samples of human DNA obtained from patients with Cystic Fibrosis were analyzed for the presence of mutations G551D, W1282X, and ΔF508 using oligos 41-52. These analyses were performed by subjecting the sample DNA to LCR following Example 9, and subsequent immunochromatography of the resulting mix following Example 6. Reagents were prepared as before (see Examples 4-6).

20 In Figure 3 is shown a photograph of nitrocellulose strips after immunochromatography. It shows the presence of amplification products specific for (spots from bottom and left to top and right) CF mutations W1282X, ΔF508, and G551D. The samples were: 1) water (no DNA), 2) patient heterozygous for G542X mutation, 3) patient heterozygous for W1282X mutation, 4) patient heterozygous for ΔF508
25 mutation, and 5) patient heterozygous for G551D mutation. No spot appears after amplification of water or G542X DNA (strips 1 and 2). Only one spot appears on strip 3, and this is located near the left of the strip (locus of *anti*-thiophene-carbazole immobilization), indicating a positive amplification of only the W1282X DNA. Only one spot appears on strip 4, and this is near the middle of the strip (locus of *anti*-fluorescein
30 immobilization), indicating a positive amplification of only ΔF508 DNA. Only one spot appears on strip 5, and this is located near the right of the strip (locus of *anti*-dansyl immobilization), indicating a positive amplification of only G551D DNA.

Although all 12 oligos were present in all the reaction tubes, permitting the amplification of DNA from all three mutations, only the specific DNA present in each
35 sample actually was amplified. Each patient was heterozygous for their particular mutation, meaning that each also carried one normal gene. In no case was the normal gene shown to be amplified by any of the oligonucleotides.

TATATTCATC ATAGGAAACA CGA

23

What is claimed is:

- 1 1. A method of performing multiplex ligase chain reaction comprising the steps
2 of:
 - 3 a. providing a reaction solution containing nucleic acid of a sample as single-
4 stranded nucleic acid, said sample putatively having one or more of a plurality of target
5 nucleic acid sequences;
 - 6 b. for each putative target sequence, providing in the reaction solution at least
7 four nucleic acid probes (a probe set), wherein: i) the first and second of said probes are
8 primary probes, and the third and fourth of said probes are secondary nucleic acid probes;
9 ii) the first probe is a single strand capable of hybridizing to a first segment of a primary
10 strand of the target nucleic acid; iii) the second probe is a single strand capable of
11 hybridizing to a second segment of said primary strand of the target nucleic acid; iv) the 5'
12 end of the first segment of said primary strand of the target is positioned relative to the 3'
13 end of the second segment of said primary strand of the target to enable joining of the first
14 probe to the second probe when said probes are hybridized to said primary strand of said
15 target nucleic acid, thus forming a reorganized primary molecule having a first portion and
16 a second portion; v) the third probe is capable of hybridizing to a first portion of the
17 reorganized primary molecule; and vi) the fourth probe is capable of hybridizing to a
18 second portion of the reorganized primary molecule, the first portion of the reorganized
19 primary molecule being positioned relative to the second portion of the reorganized primary
20 molecule to enable joining of the third probe to the fourth probe when said third and fourth
21 probes are hybridized to said reorganized primary molecule, thus forming a reorganized
22 secondary molecule; and
23 wherein for each putative target sequence said probe set is provided at a
24 concentration that enables said joining in the presence of each of the other probe sets; and
25 c. repeating the following cycle:
 - 26 i) hybridizing said probes with nucleic acid in said sample;
 - 27 ii) performing said joining to form said reorganized molecules; and
 - 28 iii) denaturing nucleic acid in said sample;
- 29 whereby with successive cycles the quantity of reorganized primary and secondary
30 molecules is increased for each putative target sequence present in the reaction solution.

2. The method according to claim 1, wherein said joining is performed by a ligase enzyme, or a ligase enzyme and a polymerase enzyme.
3. The method according to claim 1, wherein the cycle of step c is repeated from 20 to about 60 times.
4. The method according to claim 1, wherein at least one probe from each probe set carries a detectable label, each of said detectable labels being differentiable from the others.
5. The method according to claim 4, wherein said detectable labels comprise haptens which are differentiable based on the specificity of different specific binding members.
6. The method according to claim 1, wherein each of the probe sets are labeled with two distinct labels such that the reorganized molecules, when hybridized together, are labeled with two labels, at least one of which is a unique label that is different for each of the probe sets.
7. The method according to claim 6, wherein the other label is a common label, the same for each probe set.
8. The method according to claim 7, wherein the common label is used for detection and is selected from the group consisting of radioisotopes, fluorophores, chemilumiphores and haptens.
9. The method according to claim 6, wherein the unique labels comprise unique specific binding members such that each unique specific binding member is differentiable from every other specific binding member.
10. The method according to claim 9, wherein the unique labels comprise specific haptens.
11. The method according to claim 9, wherein the unique labels comprise specific hybridization probes.
12. The method according to claim 9, wherein the unique specific binding member is used to separate the reorganized molecules of one probe set from the reorganized molecules of at least one other probe set.

13. The method according to claim 12, wherein the separation is achieved by immobilizing a specific binding partner for each specific binding member at a different location on a solid phase.

14. The method according to claim 12, wherein the separation is achieved by immobilizing a specific binding partner for each specific binding member on a solid phase, said solid phase being characterized by a property which permits differentiation of one from another.

1 15. A method of detecting the presence, absence or quantity of each of a
2 plurality of target nucleic acid sequences by a multiplex ligase chain reaction comprising the
3 steps of:
4 a. providing a reaction solution containing nucleic acid of a sample as single-
5 stranded nucleic acid, said sample putatively having one or more of a plurality of target
6 nucleic acid sequences;
7 b. for each putative target sequence, providing in the reaction solution a set of
8 at least two and optionally four nucleic acid probes (a probe set), wherein: i) the first and
9 second of said probes are primary probes, and the optional third and fourth of said probes
10 are secondary nucleic acid probes; ii) the first probe is a single strand capable of
11 hybridizing to a first segment of a primary strand of the target nucleic acid; iii) the second
12 probe is a single strand capable of hybridizing to a second segment of said primary strand
13 of the target nucleic acid; iv) the 5' end of the first segment of said primary strand of the
14 target is positioned relative to the 3' end of the second segment of said primary strand of
15 the target to enable joining of the first probe to the second probe when said probes are
16 hybridized to said primary strand of said target nucleic acid, thus forming a reorganized
17 primary molecule having a first portion and a second portion; v) the third probe is capable
18 of hybridizing to a first portion of the reorganized primary molecule; and vi) the fourth
19 probe is capable of hybridizing to a second portion of the reorganized primary molecule,
20 the first portion of the reorganized primary molecule being positioned relative to the second
21 portion of the reorganized primary molecule to enable joining the third probe to the fourth
22 probe when said third and fourth probes are hybridized to said reorganized primary
23 molecule, thus forming a reorganized secondary molecule;
24 wherein at least one probe of each probe set contains a detectable label, the
25 detectable label associated with each probe set being differentiable from the detectable labels
26 associated with the other probe sets, whereby the presence, absence or quantity of each
27 putative target sequence can be determined; and

28 wherein for each putative target sequence said probe set is provided at a
29 concentration that enables said joining in the presence of each of the other probe sets; and
30 c. performing the following cycle:
31 i) hybridizing said probes with nucleic acid in said sample;
32 ii) performing said joining to form said reorganized molecules; and
33 iii) denaturing nucleic acid in said sample;
34 whereby with each cycle the quantity of reorganized primary and, optionally,
35 secondary molecules is increased for each putative target sequence present in the reaction
36 solution; and
37 d. measuring the detectable label associated with each of said probe sets as a
38 measure of the presence or quantity of target nucleic acid in the reaction solution.

16. The method according to claim 15, wherein said joining is performed by a
ligase enzyme, or a ligase enzyme and a polymerase enzyme.

17. The method according to claim 15, wherein said third and fourth probes are
provided and the cycle of step c is repeated from 10 to about 100 times.

18. The method according to claim 15, wherein the cycle of step c is repeated
from 20 to about 60 times.

19. The method according to claim 15, wherein the probes are labeled with two
labels such that the reorganized molecules are labeled with two labels, at least one of which
is a unique label that is different for each of the probe sets.

20. The method according to claim 17, wherein the probes are labeled with two
labels such that the reorganized molecules are labeled with two labels, at least one of which
is a unique label that is different for each of the probe sets and the other of which is a
common label.

21. The method according to claim 20, wherein the common label is used for
detection and is selected from the group consisting of radioisotopes, fluorophores,
chemilumiphores and haptens.

22. The method according to claim 20, wherein the unique labels comprise
haptens and wherein each unique hapten differs from every other unique hapten.

23. The method according to claim 20, wherein the unique labels comprise specific hybridization probes.

24. The method according to claim 22, wherein the unique hapten is used to separate the different reorganized molecules.

25. The method according to claim 24, wherein the separation is achieved by immobilizing a specific binding partner for each unique hapten at a different location on a solid phase.

26. The method according to claim 24, wherein the separation is achieved by immobilizing a specific binding partner for each unique hapten on a solid phase, said solid phase being characterized by a property which permits differentiation of one from another

1 27. An immunochromatographic device for multiplex detection of multiple
2 analytes, comprising
3 a strip of porous material capable of transporting fluids by capillary action, said
4 strip having at least first and second unique capture reagents immobilized thereon in first
5 and second discrete spots spaced apart from an end used to contact transport fluid, said
6 unique first and second capture reagents being specific different first and second analytes,
7 respectively,
8 wherein said second discrete spot is spaced from said first discrete spot in both
9 vertical and horizontal dimensions, vertical being the direction of fluid flow.

28. The device of claim 27 wherein three or more discrete spots are provided, and said spots are all spaced from one another in both vertical and horizontal dimensions to form a substantially linear, diagonal array of spots.

1 29. A method of performing immunochromatography, comprising:
2 providing a strip of porous material capable of transporting fluids by capillary
3 action, said strip having at least first and second unique capture reagents immobilized
4 thereon in first and second discrete spots spaced apart from an end used to contact transport
5 fluid, said unique first and second capture reagents being specific different first and second
6 analytes, respectively, wherein said second discrete spot is spaced from said first discrete
7 spot in both vertical and horizontal dimensions, vertical being the direction of fluid flow;
8 and providing a test solution suspected of containing the analyte;
9 contacting said contact end with said test solution under conditions that allow said
10 solution to be transported by capillary action at least to the most distal capture spot;
11 determining for each capture spot, whether analyte became bound to said capture
12 spot.

30 The method of claim 29, wherein at least one of said analytes is a target polynucleotide.

31 The method of claim 30, wherein said target polynucleotide is labeled with at least one hapten, said hapten and an anti-hapten antibody being used to capture the analyte at the capture spot.

INTERNATIONAL SEARCH REPORT

International application No.

PCT/US93/03034

A. CLASSIFICATION OF SUBJECT MATTER

IPC(5) : C12P 19/34; G01N 33/543

US CL : 435/91; 436/518

According to International Patent Classification (IPC) or to both national classification and IPC

B. FIELDS SEARCHED

Minimum documentation searched (classification system followed by classification symbols)

U.S. : 435/91; 436/518

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

Electronic data base consulted during the international search (name of data base and, where practicable, search terms used)

Please See Extra Sheet.

C. DOCUMENTS CONSIDERED TO BE RELEVANT

Category*	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.
Y	EP, A, 0 336 731 (Wallace) 11 October 1989, Abstract and Examples 5 and 7.	1-26
Y	EP, A, 0 364 255 (Caskey et al.) 18 April 1990, Abstract and Table 1.	1-26

Y	US, A, 4,882,269 (Schneider et al) 21 November 1989, Abstract and Figure 1a.	11, 23

Further documents are listed in the continuation of Box C.

See patent family annex.

* Special categories of cited documents:	*T	later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention
A document defining the general state of the art which is not considered to be part of particular relevance	*X*	document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone
E earlier document published on or after the international filing date	*Y*	document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art
L document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)	*A*	document member of the same patent family
O document referring to an oral disclosure, use, exhibition or other means		
P document published prior to the international filing date but later than the priority date claimed

INTERNATIONAL SEARCH REPORT

International application No.
PCT/US93/03034

Box I Observations where certain claims were found unsearchable (Continuation of item 1 of first sheet)

This international report has not been established in respect of certain claims under Article 17(2)(a) for the following reasons:

1. ☐ Claims Nos.:
because they relate to subject matter not required to be searched by this Authority, namely:
2. ☐ Claims Nos.:
because they relate to parts of the international application that do not comply with the prescribed requirements to such an extent that no meaningful international search can be carried out, specifically:
3. ☐ Claims Nos.:
because they are dependent claims and are not drafted in accordance with the second and third sentences of Rule 6.4(a).

Box II Observations where unity of invention is lacking (Continuation of item 2 of first sheet)

This International Searching Authority found multiple inventions in this international application, as follows:
(Telephone Practice)

- I. Claims 1-26, drawn to a method of performing multiplex ligase chain reaction, classified in Class 435/91.
- II. Claims 27-31, drawn to a device and method for performing immunochromatography, classified in Class 436/518.

1. ☒ As all required additional search fees were timely paid by the applicant, this international search report covers all searchable claims.
2. ☐ As all searchable claims could be searched without effort justifying an additional fee, this Authority did not invite payment of any additional fee.
3. ☐ As only some of the required additional search fees were timely paid by the applicant, this international search report covers only those claims for which fees were paid, specifically claims Nos.:
4. ☐ No required additional search fees were timely paid by the applicant. Consequently, this international search report is restricted to the invention first mentioned in the claims; it is covered by claims Nos.:

Remark on Protest

- ☐ The additional search fees were accompanied by the applicant's protest.
☐ No protest accompanied the payment of additional search fees.
